Security incident report

Section 1: Identify the network protocol involved in the incident

The network protocol involved in this incident is HTTP (Hypertext Transfer Protocol) at the application layer. Running the topdump on the network and accessing the yummyrecipesforme.com website to detect the problem, capture protocol, and traffic activity in a DNS & HTTP traffic log file provided the evidence needed to come to this conclusion. The malicious file was observed being transported using the HTTP protocol.

Section 2: Document the incident

Several customers contacted the website owner stating that when they visited the website, they were prompted to download and run a file that asked them to update their browsers. Their personal computers have been operating slowly ever since. The website owner tried logging into the web server but noticed they were locked out of their account.

The cybersecurity analyst used a sandbox environment to test the website without impacting the company network. Then, the analyst ran topdump to capture the network and protocol traffic packets produced by interacting with the website. The analyst was prompted to download a file claiming it would update the user's browser, accepted the download and ran it. The browser then redirected the analyst to a fake website (greatrecipesforme.com) that looked identical to the original site (yummyrecipesforme.com).

The cybersecurity analyst inspected the topdump log and observed that the browser initially requested the IP address for the yummyrecipesforme.com website. Once the connection with the website was established over the HTTP protocol, the analyst recalled downloading and executing the file. The logs showed a sudden change in network traffic as the browser requested a new IP resolution for the greatrecipesforme.com URL. The network traffic was then rerouted to the new IP address for the greatrecipesforme.com website.

The senior cybersecurity professional analyzed the source code for the websites and the downloaded file. The analyst discovered that an attacker had

manipulated the website to add code that prompted the users to download a malicious file disguised as a browser update. Since the website owner stated that they had been locked out of their administrator account, the team believes the attacker used a brute force attack to access the account and change the admin password. The execution of the malicious file compromised the end users' computers.

Section 3: Recommend one remediation for brute force attacks

One remediation for brute force attacks in this incident is to change the default password to a strong password using numbers and special characters. In addition, developers should hash and salt the passwords once created to make it even more difficult for brute force attacks.
